

## Introduction to Logic and Databases

R. Ramakrishnan

Database Management Systems, Gehrke-  
Ramakrishnan, 3<sup>rd</sup> ed

## Prolog Example

$$\forall x, y, z \left( \begin{array}{l} p(x, y) :- e(x, y) \\ p(x, y) :- e(x, z), p(z, y) \end{array} \right)$$

$p(\sigma, ?)$

Syntax :

Rule  $h :- b.$

Literal  $p(x, y); q([5|x], z)$

Tuple  $p(5, 6)$

Term  $[5|x]; 5; x; f(5, y)$

Predicate  $p; e; " + "; " \times " \dots$

## Why, and what

- ❖ Idea
  - If you want to compute a set of facts (tuples), just describe the set, and let the DBMS/Compiler worry about efficiency.
- ❖ Describing *what* you want
  - LOGIC PROGRAM
  - set of **RULES** + **FACTS**
- ❖ Semantics
  - Intuitively
  - Head of rule is true if (and only if) body is true.
  - Formally
  - The Least Model of program

## Model

- ❖ An '**Interpretation**'
  - A mapping: Predicate name  $\rightarrow$  Set of Facts
- ❖ A '**Model**'
  - An interpretation I such that:
    - $\forall$  "evaluable" predicate p,  $I(p) = \text{natural}(p)$
    - $\forall$  Rule  $p(t) :- q_1(t_1), \dots, q_n(t_n)$ :  
For any assignment  $\sigma$  of constants to variables,  
 $\sigma(t)$  is in  $I(p)$  IF  $\forall i, \sigma(t_i)$  is in  $I(q_i)$
- ❖ **Least Model**
  - A model I such that for every other model I',  
 $\forall$  predicate p,  $I(p) \subseteq I'(p)$

## Example

1. par(abel, adam).
2. par(abel, eve).
3. par(sem, abel).
4. anc(x,y):- anc(x,z),anc(z,y).
5. anc(x,y):- par(x,y).
6. gen(x,l):- gen(y,j), par(x,y),  
I=J+1.
7. gen(adam,1)

Evaluate predicate "+":  $+(I, J, K) \equiv I=J+K$

Least Model (Rules 1-5)

```

par(abel, adam) anc(abel, adam)
par(abel, eve)  anc(abel, eve)
par(sem, abel)  anc(sem, abel)
                anc(sem, adam)
                anc(sem, eve)
  
```

If add anc(sem, sem), is this a Model?

## Applying a rule

- ❖ If rule R and a set of facts F are given, the rule can be used to generate new facts.
- ❖ **Operator  $T_p$**   
 $T_p(F) = F \cup \{\text{all facts that can be generated in 1 step by applying rules of program } P\}$
- ❖ **Fixpoints of  $T_p$**   
A set of facts F is a fixpoint of  $T_p$  if  $F = T_p(F)$
- ❖ **Key Results**
  1. If P is a **Horn Clause program (w/o negation)**, there is a **unique least fixpoint** (obtained by starting with the empty set of facts, and applying  $T_p$ )
  2. **Least Fixpoint = Least Model**

## Stratification

- Does every program have least model?  
Not if there is **NEGATION!**  
 $p:-q, \quad q:-\neg p.$   
 2 least models: (p False, q True) and (p True, q False)

### Stratification

- $p \rightarrow q$  :  $\exists$  some rule with head q, and p in body.
- $p \rightarrow^* q$  :  $\exists$  some predicate s:  $p \rightarrow s, s \rightarrow^* q$ , or  $p \rightarrow q$
- If  $\neg p \rightarrow^* q$ , then  $q \leftarrow^* p$  and  $\neg q \leftarrow^* p$

## Stratification – Cont.

### Dependency Graph

- A **NODE** for each predicate.
- An **ARC** (directed) from p to q if there is rule with head predicate q and body predicate p.
- Note:**
  - For simplicity, we don't consider programs with 'V' in rule heads.
  - If p is **NEGATED**, the arc is labeled '¬'

- A Program is **STRATIFIED** if the dependency graph has no cycle passing through an arc labeled '¬'.

## Stratification - Cont.

### Strata

- Merge all nodes in cycles with no ¬ arcs to obtain a DAG. Each node in the DAG is called a **STRATUM** or **LAYER**.
- Without loss of generality, assume a topological sort that orders all strata:  $L_1, L_2, \dots, L_n$ . Thus, no predicate in  $L_i$  is used to define a predicate in  $L_j$  if  $i > j$ .

### Idea

- Evaluate layer-by-layer, from  $L_1$  to  $L_n$ . (Least Fixpoint evaluation within each layer.)
- Guaranteed to lead to a unique result.

### Question

- Which has higher priority for minimization,  $L_1$  or  $L_n$ ?

## Stratified Models

- If predicate p is in  $L_i$ , q is in  $L_j$ ,  $i > j$ , then every p-fact has lower priority than any q fact.
- Model N is "smaller" than model M if for each fact A in N-M, there is a fact B in M-N such that A has lower priority than B.
- Theorem:** If P is a stratified program
  - There is a "least" model M for P
  - M = layer-by-layer least fixpoint

## Example

$unanc(x,y):- person(x), person(y), \neg anc(x,y).$   
 $anc(x,y):- anc(x,z), par(z,y).$   
 $anc(x,x):- person(x).$

$p(s):- \neg q(s).$   
 $q(s):- \neg p(s).$

$p(0).$   
 $p(x):- \neg p(s(x)).$

$even(0).$   
 $even(s(x)):- \neg even(x).$

## Negation

### Prolog:

- Negation as failure.
- Why isn't this appropriate?

### Example

$\{ rich(x) \vee tv\_evangelist(x) :- famous(x).$   
 $famous(Forbes).$   
 $Prof(Raghu).$

There are 2 minimal models. Note that 'V' is treated as an exclusive or; this is a consequence of minimal model semantics.

$\{ rich(x) :- famous(x), \neg tv\_evangelist(x)$   
 $famous(Forbes).$   
 $prof(Raghu).$

Which minimal model is better? Intuitively, we place a higher priority on minimizing the relation tv\_evangelist. (The fewer the better).

## Properties of a query

### ❖ Safety

- Finite set of answers.

e.g.  $>(x,5)?$  (unsafe)

e.g.  $\text{like}(x,y):- \text{nice}(x).$

$\text{nice}(\text{john}).$

$\text{like}(\text{john},u)?$  (safe)

### plus

$\text{good\_sal}(z):- z>40k, z<60k.$

$\text{like}(\text{john},u)?$  (unsafe)

### ❖ Range-Restriction

- For every rule, every variable  $x$  in head also appears in positive body literal.  
This a sufficient condition for safety of Datalog programs.
- Definition: DATALOG - No function symbols or arithmetic.
